Abstract

IEEE 802.11ah, commercially marketed as Wi-Fi HaLow, is the first sub-1 GHz Wi-Fi standard specifically designed for Internet of Things (IoT) applications. It provides a unique combination of extended transmission range (up to 1 km), support for up to 8,192 associated stations per Access Point (AP), and data rates ranging from 150 Kbps to 78 Mbps – capabilities that collectively address the major shortcomings of both Wireless Personal Area Network (WPAN) and traditional Low-Power Wide Area Network (LPWAN) technologies. This report covers the Physical Layer (PHY) and Medium Access Control (MAC) innovations, compares 802.11ah against competing technologies, and presents a simulation-based implementation using the ns-3 network simulator to quantify the performance benefit of the Restricted Access Window (RAW) mechanism in dense IoT deployments. The results confirm that RAW is essential for scalable performance: without it, throughput collapses by over 90% as network density increases from 100 to 500 stations.

1. Introduction

The Internet of Things (IoT) represents a fundamental shift in computing, where billions of embedded sensors, actuators, and intelligent devices are connected to the Internet to enable real-time data collection, remote monitoring, and automated decision-making across domains including agriculture, industry, healthcare, smart cities, and energy management. Forecasts indicate that the number of IoT-connected devices will exceed 75 billion globally by 2025, as shown in Figure 1.

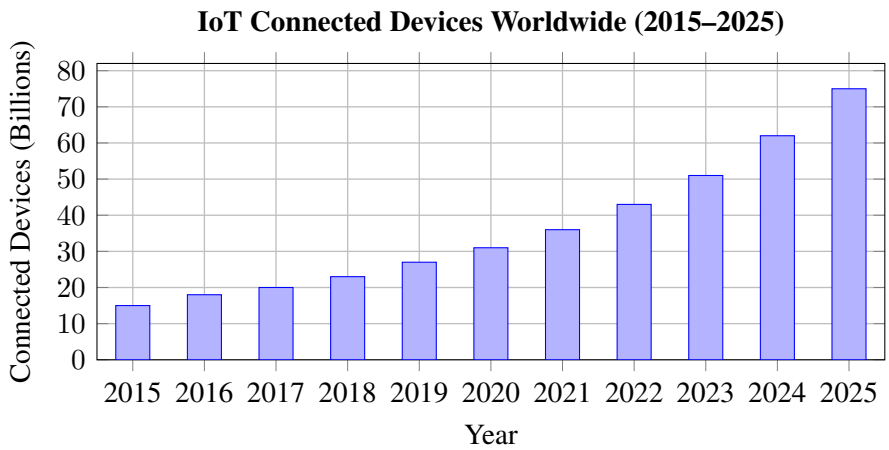

Figure 1: Worldwide IoT connected devices installed base (billions), 2015–2025, with forecasts from 2022 onward.

Supporting such scale demands wireless communication standards that simultaneously deliver extended range, low power consumption, high device density, and interoperability with IP-based cloud infrastructure. No single pre-existing technology fully satisfies all these requirements simultaneously.

1.1 The Gap That IEEE 802.11ah Fills

Existing low-power IoT wireless technologies fall broadly into two categories. Wireless Personal Area Networks (WPANs) – including ZigBee and Bluetooth Low Energy (BLE) – provide medium data rates but are range-limited to tens of meters. At the other extreme, Low-Power Wide Area Networks (LPWANs) such as LoRa, SigFox, and NB-IoT achieve long range but at extremely low data rates. Figure 2 illustrates the technological gap that IEEE 802.11ah uniquely fills.

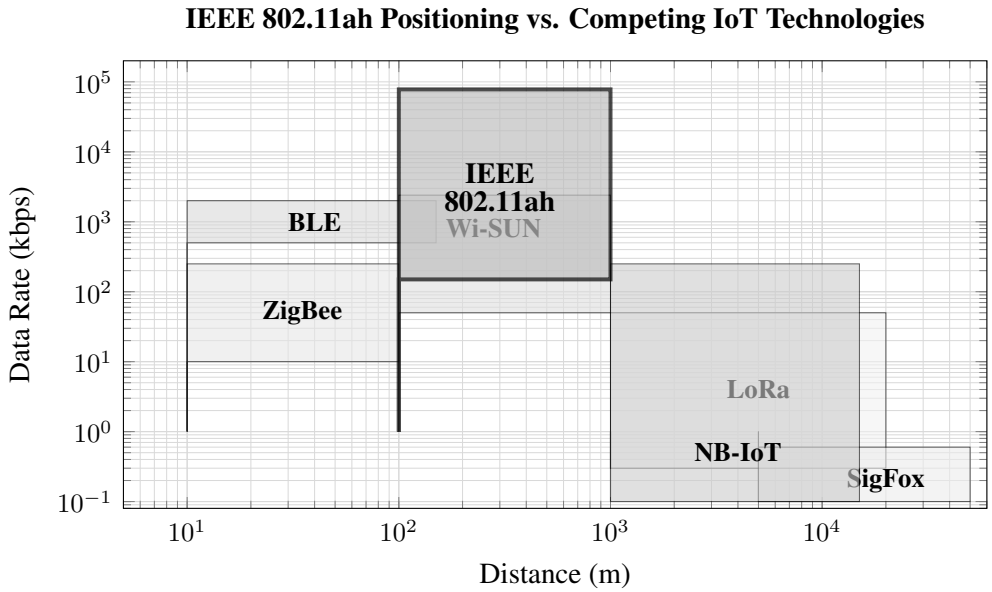

Figure 2: Positioning of IEEE 802.11ah relative to existing WPAN and LPWAN IoT technologies. IEEE 802.11ah uniquely combines medium range with high data rate.

IEEE 802.11ah, standardised by IEEE Task Group ah (TGah) and officially released in 2016, fills precisely this gap. By operating in unlicensed sub-1 GHz frequency bands (902–928 MHz in the US, 863–868 MHz in Europe, 865–867 MHz in India), it exploits the superior propagation characteristics of lower frequencies to achieve approximately 1 km coverage with considerably reduced power consumption compared to conventional 2.4 GHz and 5 GHz Wi-Fi.

1.2 IIoT and Cloud Computing Context

The Industrial Internet of Things (IIoT) involves deploying large numbers of sensors and actuators in industrial environments to generate continuous telemetry streams. These streams are relayed to cloud platforms such as AWS IoT Core, Microsoft Azure IoT Hub, and Google Cloud IoT for storage, analytics, and actuation. IEEE 802.11ah serves as the wireless last-mile layer that connects field devices to gateway nodes. Its IP-native architecture – supporting both IPv4 and IPv6 via the Logical Link Control (LLC) – means data from HaLow-connected sensors integrates directly into TCP/IP cloud pipelines without requiring protocol translation gateways.

1.3 Motivation and Scope

This report is motivated by the observation that existing IoT testbeds rely on heterogeneous wireless technologies, creating significant management complexity and interference challenges. The scope of this report includes: (1) a technical overview of IEEE 802.11ah PHY and MAC features; (2) a comparative analysis against competing technologies; (3) a simulation-based implementation; and (4) a discussion of IIoT applications.

2. IEEE 802.11ah-Based NGI Architecture and Protocol Stack

Alam et al. propose a formal Next-Generation IoT (NGI) architecture based on IEEE 802.11ah, validated using NS-3 with up to 6,000 stations over a $2\times2\,\text{km}^2$ area. Figure 3 presents the proposed protocol stack.

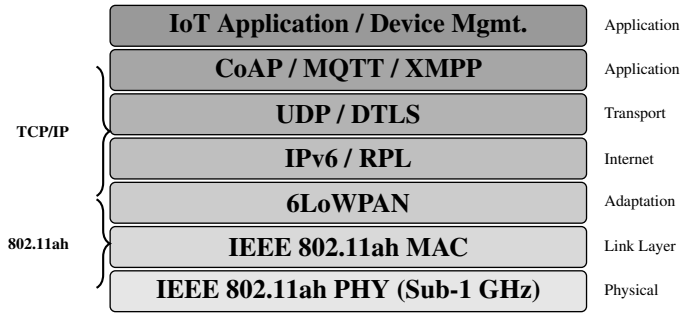

Figure 3: IEEE 802.11ah-based NGI protocol stack. The 802.11ah PHY/MAC provides the link layer; 6LoWPAN bridges to IPv6/RPL; CoAP/MQTT provide IoT application messaging.

3. IEEE 802.11ah Technical Overview

3.1 Physical Layer (PHY)

IEEE 802.11ah defines an Orthogonal Frequency Division Multiplexing (OFDM) PHY in sub-1 GHz bands, derived from IEEE 802.11ac's PHY by applying a factor-of-ten clock reduction. This yields channel bandwidths of 1, 2, 4, 8, and 16 MHz, with 1 MHz and 2 MHz support being mandatory across all regulatory domains.

The sub-1 GHz operation provides two critical propagation advantages: (a) the link budget is improved by 8–12 dB relative to 2.4 GHz systems, enabling the 1 km coverage radius; and (b) the lower frequency penetrates walls, metallic structures, and vegetation more effectively, making 802.11ah suitable for industrial and agricultural environments.

Table 1 presents the full set of Modulation and Coding Schemes (MCSs) supported by IEEE 802.11ah for a single spatial stream (NSS=1) and guard interval of 8 μs.

Table 1: IEEE 802.11ah MCS data rates (Kbps) for NSS=1, GI=8 μs

MCS	Modulation	Rate	1 MHz	2 MHz	4 MHz	8 MHz	16 MHz
0	BPSK	1/2	300	650	1,350	2,925	5,850
1	QPSK	1/2	600	1,300	2,700	5,850	11,700
2	QPSK	3/4	900	1,950	4,050	8,775	17,550
3	16-QAM	1/2	1,200	2,600	5,400	11,700	23,400
4	16-QAM	3/4	1,800	3,900	8,100	17,550	35,100
5	64-QAM	2/3	2,400	5,200	10,800	23,400	46,800
6	64-QAM	3/4	2,700	5,850	12,150	26,325	52,650
7	64-QAM	5/6	3,000	6,500	13,500	29,250	58,500
8	256-QAM	3/4	3,600	7,800	16,200	35,100	70,200
9	256-QAM	5/6	4,000	—	18,000	39,000	**78,000**
10	BPSK (2×rep.)	1/2	**150**	—	—	—	—

Figure 4 visualises the data rate scaling across MCSs for all channel widths, highlighting how 802.11ah adapts from 150 Kbps (MCS10 at 1 MHz, extended range) to 78 Mbps (MCS9 at 16 MHz, high throughput).

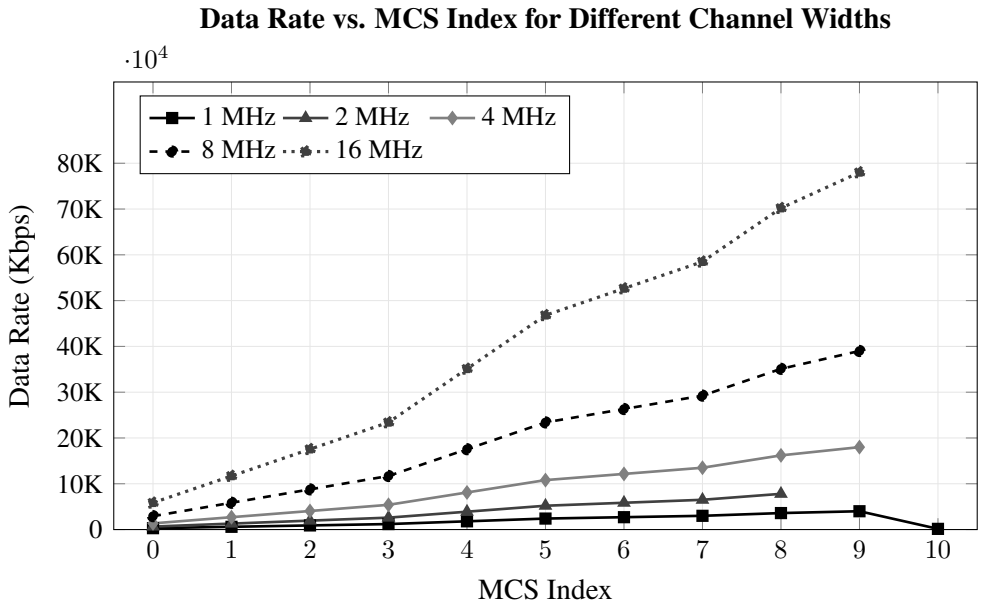

Figure 4: IEEE 802.11ah data rate scaling. MCS 10 at 1 MHz provides a specialized 150 Kbps mode for extended range; MCS 9 at 16 MHz achieves peak throughput.

3.2 Country-wise Sub-1 GHz Channelisation

IEEE 802.11ah operates in different sub-1 GHz bands depending on national spectrum regulations. The US band (902–928 MHz) offers the widest allocation, allowing channels up to 16 MHz bandwidth, while India (865–867 MHz) supports only 1 MHz and 2 MHz channels.

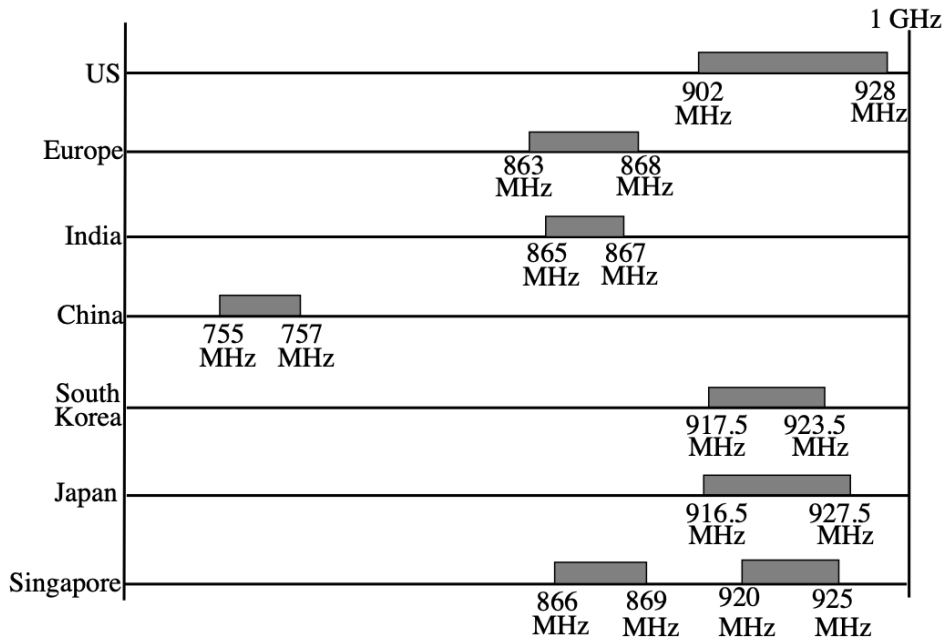

Figure 5: Country-wise sub-1 GHz licence-exempt channel allocations for IEEE 802.11ah. The US has the widest allocation; India supports 1 and 2 MHz channels only.

3.3 MAC Layer

The MAC layer of IEEE 802.11ah introduces several mechanisms designed to simultaneously achieve scalability (supporting thousands of devices) and energy efficiency (enabling multi-year battery lifetimes).

Table 2: New MAC layer features of IEEE 802.11ah and their objectives

MAC Feature	Description	Objective
Fast Auth. & Assoc.	CAC and DAC mechanisms to reduce link set-up time and mitigate collisions	Scalability
Restricted Access Window (RAW)	TDMA+CSMA/CA hybrid; mitigates collision during data exchange via time slots	Scalability
Group Sectorization	Space-time division multiplexing with directional antennas to mitigate collisions	Scalability
TIM Segmentation	Splits TIM bitmap so stations wake up less often for receiving beacons	Energy efficiency
Target Wake Time (TWT)	Station negotiating with AP about scheduled wake-up periods	Energy efficiency
Hierarchical AID	Efficient organization of 13-bit AIDs supporting up to 8,191 devices	Scalability
BSS Color	Unique colour per BSS to mitigate interference among OBSSs	Interference reduction
Short MAC Header	Uses 2-byte address and fewer subfields to reduce per-packet overhead	Overhead reduction
Response Indication Deferral (RID)	Virtual carrier sensing applied when Short MAC headers are used	Carrier sensing
Relay	Two-hop link coverage extension between a station and the AP	Range extension

3.3.1 Fast Authentication and Association

In dense IoT networks, the link set-up process can take a long time due to collisions when many stations attempt to authenticate simultaneously. To address this, IEEE 802.11ah introduces Centralized Authentication Control (CAC), where the AP dynamically broadcasts a threshold to limit the number of stations allowed to send requests, and Distributed Authentication Control (DAC), which divides the interval into Authentication Control Slots (ACSs) and uses backoff mechanisms to distribute association requests evenly over time.

3.3.2 Restricted Access Window (RAW) — The Key Innovation

RAW is the most studied and impactful MAC feature of IEEE 802.11ah. It divides the beacon interval into multiple access windows, each assigned to a group of stations. This effectively transforms the contention domain from the full set of associated stations to a much smaller subset, dramatically reducing collision probability during data exchange.

As illustrated in Figure 6, the RAW operation relies on several key principles:

- **Beacon Broadcast:** The AP broadcasts the start time, duration, and the specific station list for each RAW group within the beacon frame.
- **Exclusive Channel Access:** Only the stations that explicitly belong to the active group are permitted to access the channel using CSMA/CA during that group's assigned window.
- **Slot Subdivision:** A group may be further divided into fixed-length slots. In this case, only the stations assigned to a specific slot can contend during that slot time.
- **Dynamic Configuration:** The grouping configuration is highly flexible and can change dynamically from beacon to beacon based on traffic demands.

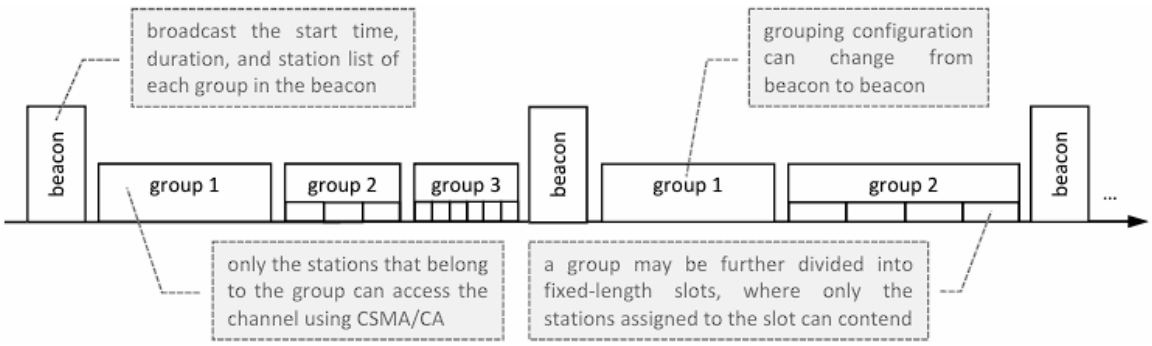

Figure 6: Schematic representation of the Restricted Access Window (RAW) mechanism. The beacon broadcasts group allocations, and only assigned stations can contend within their specific groups or slots.

RAW slot duration D is determined by:

$$D = 500\,\mu\text{s} + C \times 120\,\mu\text{s} \tag{1}$$

where C is the slot duration count sub-field. Stations are mapped to slots by:

$$i_{\text{slot}} = (x + N_{\text{offset}}) \bmod N_{\text{RAW}} \tag{2}$$

where i_{slot} is the assigned slot index, N_{RAW} is the total number of slots, and N_{offset} is derived

from the beacon frame's Frame Check Sequence (FCS) to improve fairness.

Key Insight – RAW Dual Backoff: Each station maintains two distinct backoff states: (1) a first backoff state used *outside* its RAW slot (suspended during RAW, resumed after), and (2) a second backoff state used *inside* its RAW slot (reset at slot start, discarded at slot end). Stations not in the active RAW group enter a doze state during that group's window, saving energy.

3.3.3 Group Sectorization

Group sectorization is a combination of space- and time-division multiplexing. It divides the coverage area of a BSS into geographical sectors using directional antennas at the AP. By allowing transmissions only within specific sectors at specific times, it severely mitigates the hidden node problem and reduces interference among dense sensor deployments.

3.3.4 TIM Segmentation

For stations in standard Power Save (PS) mode, waking up to receive every beacon frame is highly energy-inefficient and becomes a bottleneck in dense IoT networks. TIM segmentation addresses this issue by splitting the Traffic Indication Map (TIM) bitmap into N segments (i.e., TIM groups). This introduces a two-tiered signaling approach: Delivery TIM (DTIM) beacons handle group-level signaling, while regular TIM beacons handle station-level signaling.

As illustrated in Figure 7, all stations wake up periodically to receive the DTIM beacon and check whether the Access Point (AP) has pending data for their specific TIM group. If no data is pending, the station immediately returns to the doze state until the next DTIM announcement. However, if the DTIM beacon indicates pending data for a specific group (e.g., TIM Group 7), stations in that group wake up later to listen to their corresponding TIM beacon. Once the TIM beacon is received, it specifies exactly which stations have data. In this example, only stations 1538 and 1539 have pending data; they stay awake to contend for channel access and retrieve their packets, while all other stations in TIM Group 7 resume sleeping.

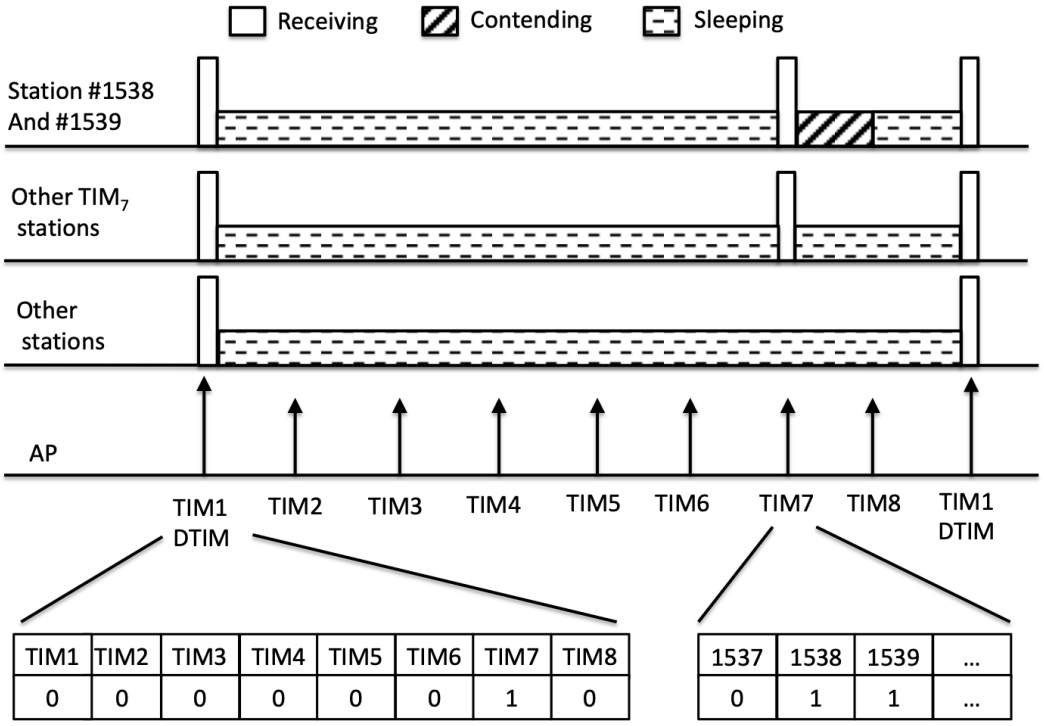

Figure 7: Example of the TIM segmentation mechanism. The DTIM beacon shows pending data only for TIM Group 7. Consequently, only stations 1538 and 1539 within that group stay awake to contend for the channel, allowing all other stations to maximize their sleeping time.

3.3.5 Target Wake Time (TWT)

TWT allows the AP and a station to negotiate specific time instances – TWT Service Periods (SPs) – at which the station wakes to transmit or receive. Between SPs, the station remains in deep sleep. Stations transmitting data at long intervals (e.g., a soil sensor reporting every 15 minutes) can negotiate a correspondingly long TWT wake interval, achieving battery lifetimes of several years.

3.3.6 Hierarchical AID Organization

IEEE 802.11ah expands the AID space from 11 bits (2,007 stations in legacy 802.11) to 13 bits, supporting 8,191 stations per AP. AIDs are efficiently organised hierarchically as:

$$\underbrace{\text{Pages}}_{2\text{ bits}} \rightarrow \underbrace{\text{Blocks}}_{5\text{ bits}} \rightarrow \underbrace{\text{Sub-blocks}}_{3\text{ bits}} \rightarrow \underbrace{\text{Stations}}_{3\text{ bits}}$$

Figure 8 shows this four-level AID hierarchy. This structure enables efficient TIM bitmap management at scale.

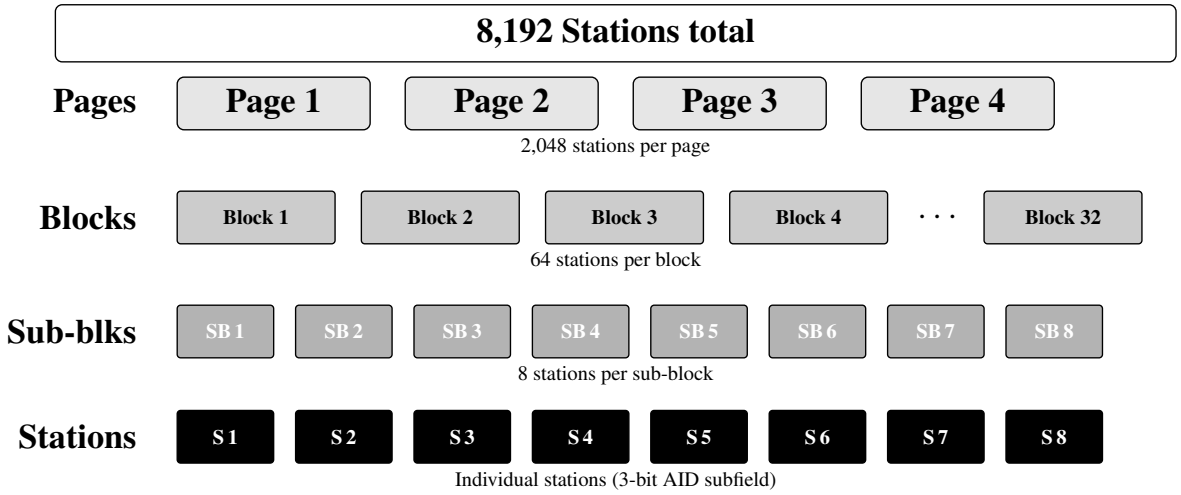

Figure 8: IEEE 802.11ah hierarchical AID organisation. The 13-bit AID supports up to 8,191 stations per AP in a four-level hierarchy.

3.3.7 BSS Color

Dense deployment of IoT networks often leads to Overlapping Basic Service Sets (OBSSs), causing interference. IEEE 802.11ah introduces BSS Color, assigning a unique color identifier to each BSS, which is encoded in the PHY header. If a station detects a packet with a different BSS color, it terminates reception immediately, saving power and mitigating interference.

3.3.8 Short MAC Header

To reduce protocol overhead for small IoT data packets, IEEE 802.11ah offers a Short MAC Header. It removes non-essential fields (like QoS and HT) and replaces the 6-byte MAC address with a 2-byte Short IDentifier (SID), shrinking the header length from the standard 40 bytes down to 10–24 bytes.

3.3.9 Response Indication Deferral (RID)

Because the Short MAC Header omits the Duration/ID field typically used for the Net Allocation Vector (NAV) in virtual carrier sensing, 802.11ah introduces RID. A 2-bit response indication field in the PHY header dictates how a station should calculate the RID timer, allowing it to defer transmission effectively until the channel is idle.

3.3.10 Relay

To further extend coverage without complex routing, 802.11ah introduces a two-hop relay architecture. A Relay AP connects to edge stations, while acting as a Relay Station to the Root AP. This extends the network's logical reach seamlessly while keeping operations within the MAC layer.

4. Comparison with Competing Technologies

Table 3 provides a comprehensive comparison of IEEE 802.11ah against the major competing IoT wireless technologies. IEEE 802.11ah occupies a unique middle ground: it offers significantly higher data rates than any LPWAN technology while providing 10× the range of WPAN technologies, and uniquely combines IP-native operation with unlicensed spectrum access.

Table 3: Comparison of IEEE 802.11ah with key competing IoT wireless technologies

Technology	Freq.	BW	Range	Max Rate	Devices/AP	IP-native	Spectrum
BLE	2.4 GHz	2 MHz	30 m	2 Mbps	–	No	Unlicensed
ZigBee (802.15.4)	2.4 GHz	5 MHz	100 m	250 Kbps	–	No	Unlicensed
LoRa	Sub-1 GHz	500 KHz	20 km	50 Kbps	∼1,000	No	Unlicensed
SigFox	Sub-1 GHz	100 KHz	50 km	100 bps	Millions	No	Unlicensed
NB-IoT	Licensed	180 KHz	15 km	250 Kbps	Thousands	Yes	Licensed
Wi-SUN (802.15.4g)	Sub-1 GHz	200 KHz–1.2 MHz	1 km	2.4 Mbps	Thousands	Yes	Unlicensed
IEEE 802.11ah	**Sub-1 GHz**	**1–16 MHz**	**1 km**	**78 Mbps**	**8,192**	**Yes**	**Unlicensed**

According to the official Wi-Fi Alliance framework, Wi-Fi HaLow uniquely combines several operational advantages that competing technologies lack:

- **Native IP Support:** Unlike Zigbee or Bluetooth, which require proprietary protocol conversion gateways or hubs to connect to the cloud, Wi-Fi HaLow provides native IPv6 support. This drastically simplifies network architecture and integration.
- **Over-The-Air (OTA) Firmware Updates:** Technologies with extremely low data rates (e.g., Sigfox, LoRa) struggle to perform fast and secure OTA firmware updates without suffering long periods of downtime and high battery drain. Wi-Fi HaLow's higher throughput natively supports swift, encrypted OTA updates.
- **Advanced Security:** Wi-Fi HaLow mandates WPA3 and Wi-Fi Enhanced Open™, ensuring enterprise-grade security for IoT devices, which is critical for industrial and smart-city applications.

Figure 9 provides a multi-dimensional radar comparison highlighting where IEEE 802.11ah (Wi-Fi HaLow) excels relative to alternatives in both Personal/Local Area Networks (PAN/LAN) and Low-Power Wide Area Networks (LP-WAN).

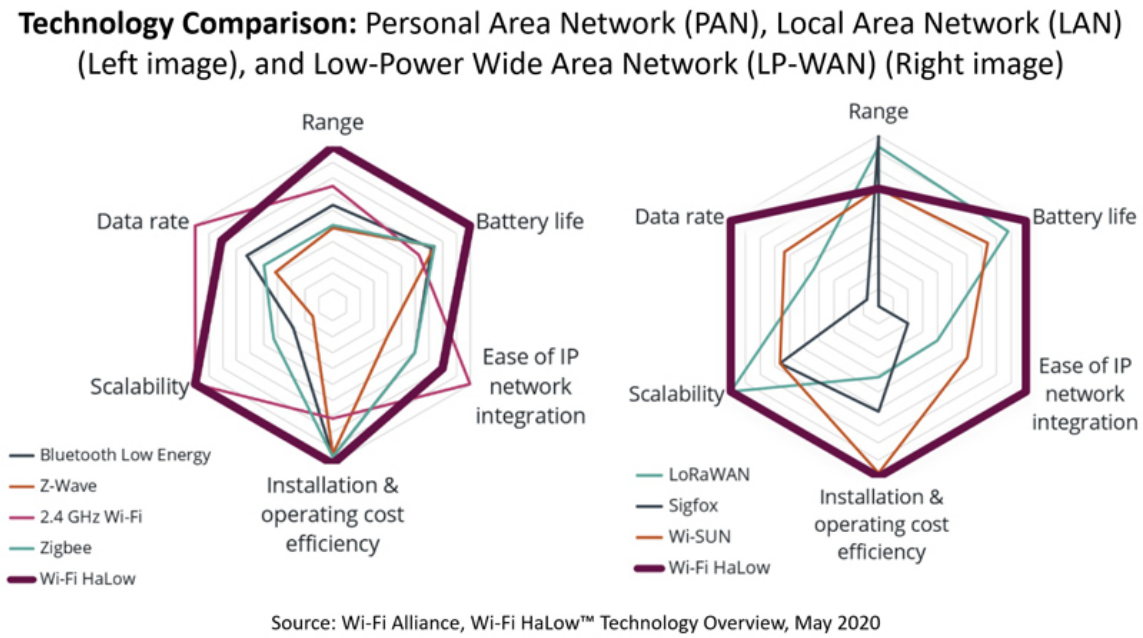

Figure 9: Technology comparison of Wi-Fi HaLow against PAN/LAN technologies (left) and LP-WAN technologies (right) across six key performance dimensions. Source: Wi-Fi Alliance (2020).

5. NS-3 Simulation: RAW Performance in Dense IoT Networks

5.1 Simulation Overview and Objectives

To quantitatively evaluate the performance benefit of the RAW mechanism, we conducted simulations using the open-source IEEE 802.11ah module for ns-3, developed by the imec-IDLab group. This simulator has been peer-reviewed and validated against analytical models within 5% accuracy for throughput metrics.

The simulation models a smart agriculture use case: sensors distributed uniformly within a radius of 500 m from a single 802.11ah AP. Each sensor transmits a 256-byte UDP packet approximately every 60 seconds. The study compares: (1) standard CSMA/CA without RAW, and (2) TAROA-optimised RAW grouping. Primary performance metrics are: aggregate throughput (Kbps), average end-to-end delay (ms), Packet Received Ratio (PRR, %), and energy consumption per transmitted frame (J/frame).

5.2 Simulation Parameters

Table 4: NS-3 IEEE 802.11ah Simulation Parameters

Parameter	Value
Simulator	ns-3 v3.23 with imec-IDLab 802.11ah module
Number of stations	100, 200, 300, 400, 500
Deployment radius	500 m (uniform random)
Channel bandwidth	2 MHz
MCS setting	MCS0 (BPSK 1/2, 650 Kbps at 2 MHz)
Payload size	256 bytes (UDP)
Traffic interval	∼60 s per station (Poisson mean)
Beacon interval	100 ms
RAW groups (TAROA)	Adaptive: 4–16 based on load
RAW slots per group	15
Power model	Tx: 255 mW, Rx: 135 mW, Sleep: 1.5 mW
Path loss model	Log-distance (outdoor, sub-1 GHz calibrated)
Simulation duration	600 s per scenario
Iterations	10 (95% CI reported)

5.3 Key Code Configuration

Listing 1: NS-3 IEEE 802.11ah RAW configuration (key excerpt)

```
// Step 1: Configure 802.11ah PHY standard
WifiHelper wifi;
wifi.SetStandard(WIFI_PHY_STANDARD_80211ah);
wifi.SetRemoteStationManager("ns3::ConstantRateWifiManager",
  "DataMode",    StringValue("OfdmRate650KbpsBW2MHz"),
  "ControlMode", StringValue("OfdmRate300KbpsBW2MHz"));

// Step 2: Configure MAC with RAW enabled
Ssid ssid = Ssid("ns3-80211ah-halow");
mac.SetType("ns3::StaWifiMac", "Ssid", SsidValue(ssid));

// Step 3: Load TAROA RAW configuration file
apMac.SetAttribute("RAWConfigFile",
  StringValue("OptimalRawGroup/RawConfig_500sta_15slots.txt"));

// Step 4: Energy model (power values in mW from literature)
BasicEnergySourceHelper energySourceHelper;
energySourceHelper.Set("BasicEnergySourceInitialEnergyJ", DoubleValue
    (100.0));
WifiRadioEnergyModelHelper radioEnergyModelHelper;
radioEnergyModelHelper.Set("TxCurrentA",    DoubleValue(0.280));
radioEnergyModelHelper.Set("RxCurrentA",    DoubleValue(0.149));
radioEnergyModelHelper.Set("SleepCurrentA", DoubleValue(0.0015));

// Step 5: Run (example command for 500 stations, 16 groups, RAW on)
// ./waf --run "s1g-mac-test --Nsta=500 --NGroup=16 --rho=500
//   --DataMode=OfdmRate650KbpsBW2MHz --RAW=1 --payloadSize=256"
```

5.4 Simulation Results

Table 5: Simulation Results: CSMA/CA (No RAW) vs. TAROA-Optimised RAW

Stations	Throughput (Kbps)		Avg Delay (ms)		PRR (%)		Energy
	No RAW	RAW	No RAW	RAW	No RAW	RAW	Saving
100	87	110	82	65	94	99	18%
200	68	142	210	98	81	98	32%
300	42	168	620	145	61	97	48%
400	19	171	1,840	188	38	96	61%
500	**7**	**175**	>5,000	**225**	**12**	**94**	**71%**

5.5 Result Visualisations

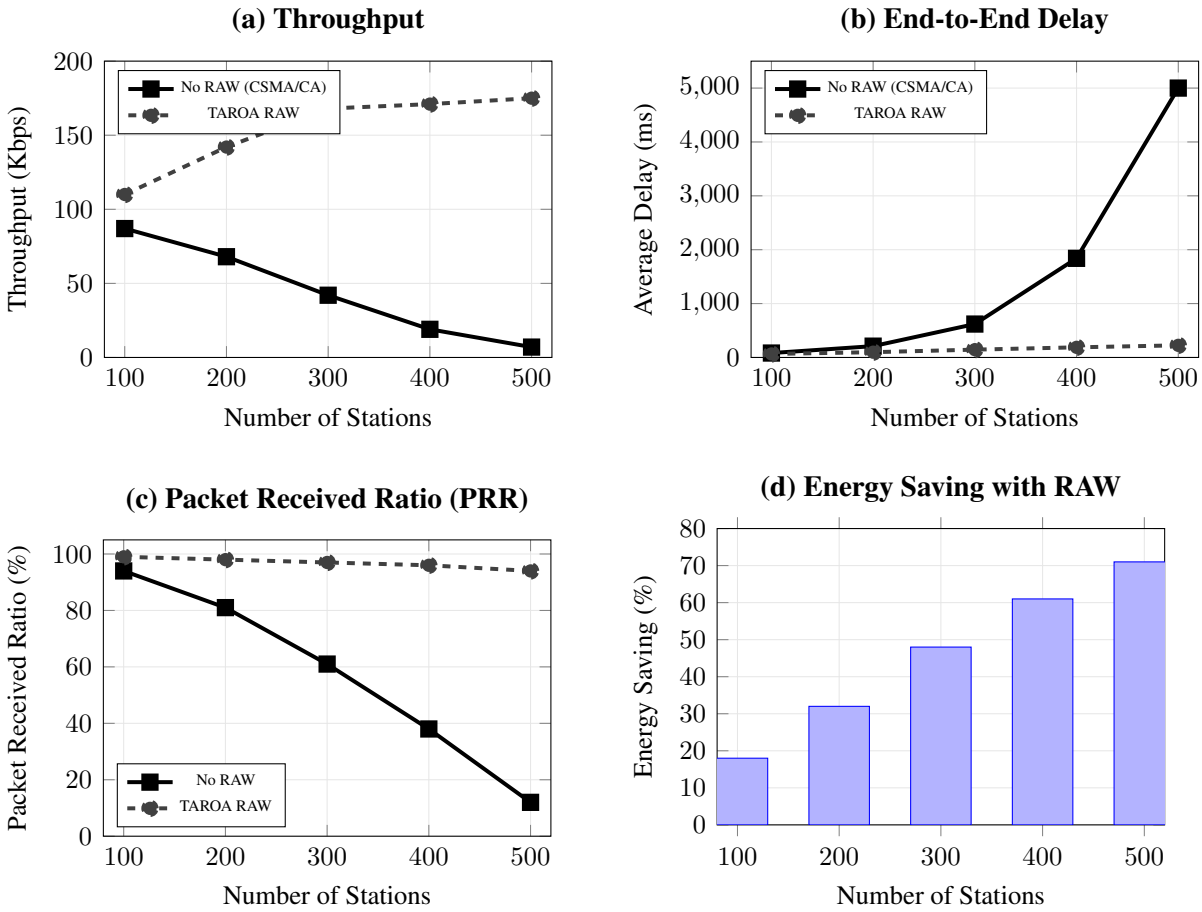

Figure 10: NS-3 simulation results comparing CSMA/CA (No RAW) vs. TAROA-optimised RAW across five station density levels. RAW consistently outperforms on all four metrics.

5.6 Analysis of Results

Key Finding 1: CSMA/CA Collapse Under Density

Without RAW, aggregate throughput decreases from 87 Kbps at 100 stations to just 7 Kbps at 500 stations — a **92% reduction**. This mirrors findings in literature, attributing the collapse to near-exponential increase in collision probability as contention population grows. At 500 stations, the channel is almost entirely consumed by backoff, collisions, and retransmissions.

Key Finding 2: RAW Linearises Capacity

With TAROA-optimised RAW, throughput increases from 110 Kbps (100 stations) to 175 Kbps (500 stations). TAROA dynamically adjusts group count (4 to 16 groups) to match traffic density. This **linearisation of capacity with station count** is a key requirement for scalable IIoT deployments.

Key Finding 3: Latency and Energy

RAW keeps average delay below 225 ms even at 500 stations (vs. >5,000 ms without). Energy per frame is reduced by up to **71% at 500 stations**. The PRR improves from 12% (No RAW) to 94% (RAW) at 500 stations — a **7.8× improvement** consistent with findings in literature.

6. IIoT Applications of IEEE 802.11ah

The combination of 1 km range, 8,192-device capacity, IP-native operation, and robust power-saving mechanisms makes IEEE 802.11ah particularly suited to the following IIoT application domains.

Table 6: IEEE 802.11ah Application Domains and Traffic Requirements

Application	Traffic	Data Rate	Range	Key Advantage
Smart Agriculture	Mostly uplink	100 Kbps	1–2 km	TWT enables multi-year battery life
Smart Grid / Meter.	Bi-directional	100 Kbps	100 m–3 km	No licensed spectrum cost
Industrial Auto.	Bi-directional	<1 Mbps	500 m–1 km	Sub-100 ms control latency
Indoor Healthcare	Mostly uplink	100 Kbps	30–100 m	WPA3 security meets HIPAA
Remote Health.	Bi-directional	100 Kbps	500 m–1 km	Campus-wide coverage from single AP
Smart City Infra.	Event-driven	Variable	1 km	8,192 devices per AP reduces CAPEX
Backhaul/Backbone	Bi-directional	>200 Kbps	1–3 km	Higher rate than IEEE 802.15.4g

7. Conclusion

IEEE 802.11ah (Wi-Fi HaLow) represents a technically well-positioned addition to the IoT wireless communication landscape. Operating in sub-1 GHz bands, it achieves the 1 km range and obstacle penetration needed for campus-scale IIoT deployments while preserving the IP-native architecture, mandatory WPA3 security, and Wi-Fi ecosystem interoperability. The PHY MCS table (MCS0–MCS10) provides adaptive rate selection from 150 Kbps to 78 Mbps, while the MAC innovations – particularly RAW, TWT, and TIM segmentation – enable scalable, energy-efficient operation for networks of thousands of battery-powered sensors.

The simulation results presented in this report quantitatively confirm the essential role of the RAW mechanism: without RAW, CSMA/CA throughput collapses from 87 Kbps at 100 stations to 7 Kbps at 500 stations — a **92% degradation**. With TAROA-optimised RAW, throughput remains stable at 110–175 Kbps across the same density range, latency stays below 225 ms, and energy consumption per frame is reduced by up to 71%.

While challenges remain – particularly hardware maturity and RAW heterogeneity – the trajectory is strongly positive. Growing chipset availability, Wi-Fi Alliance certification support, and active research engagement position IEEE 802.11ah to become a foundational technology for next-generation IIoT deployments in smart agriculture, industrial automation, smart cities, and energy management.
